SCIENCE : DISCOVERIES

The End of Theory: The Data Deluge Makes the Scientific Method Obsolete

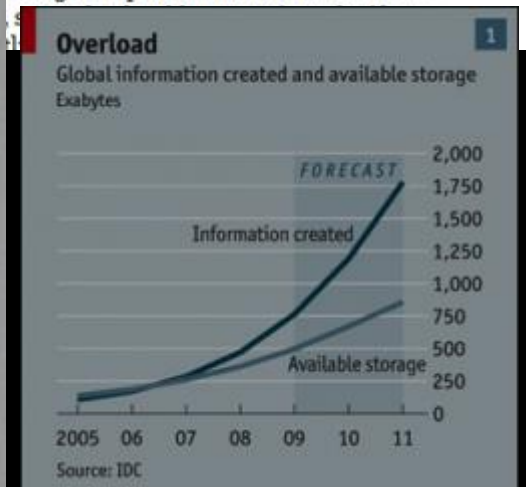
By Chris Anderson 06.23.08

Illustration: Marian Bantjes

THE PETABYTE AGE:

"All models are wrong, but some are useful."

imed statistician George Box 30 years ago, and ght. But what choice did we have? Only models, nological equations to theories of human



The Next Scientific Revolution

The Four Paradigms of Science

THEORY
Beginning in ancient Greece and China, people tried to explain their observations through natural laws instead of supernatural causes.

EXPERIMENTATION
By the 17th century, scientists like Isaac Newton tried to make predictions for new phenomena and would verify hypotheses by conducting experiments.

COMPUTATION AND SIMULATION
The advent of high-performance computers in the latter half of the 20th century allowed scientists to explore regimes inaccessible to experiment and theory, such as climate modeling or galaxy formation, by numerically solving systems of equations on a large scale and in fine detail.

DATA MINING
Using more-powerful computers, scientists begin with the data and direct programs to mine enormous databases for relationships. In essence, they use computers to discover the rules by studying the data.

Data's shameful neglect

Research canno

Brooks Hanson is Deputy Editor for physical sciences at

Making Data Maximally Available

Sharing research data to improve public health

The purpose of medical research is to analyse and understand health and disease. A key and expensive element is the study of populations to explore how interactions between behaviour and environment, in the context of genetic diversity, determine causation and variation in

that every last ounce of knowledge will be wrung from the research.

Ensuring data are made widely available to the research community accelerates the pace of discovery and enhances the efficiency of the research enterprise.

DNA microarrays allow researchers to analyse the expression of a huge number of genes simultaneously.

GENOMICS

Gene data to hit milestone

With close to one million gene-expression data sets now in publi researchers can identify disease trends without ever having to e

BY MONYA BAKER

Purvesh Khatri sits in front of an oversized computer screen, trawling for treasure in a sea of genetic data. Entering the search term 'breast cancer' into a public repository called the Gene Expression Omnibus (GEO), the postdoctoral researcher retrieves a list of 1,170 experiments, representing nearly 33,000 samples and a hoard of gene-expression data that could reveal previously unseen patterns.

That is exactly the kind of search that led Khatri's boss, Atul Butte, a bioinformatician at the Stanford School of Medicine in California, to identify a new drug target for diabetes. After downloading data from 130 gene-expression

for discovery," he says. Those are for validating hypotheses. The beauty of analysing data from multiple experiments is that biases and artefacts should cancel out between data sets, helping true relationships to stand out, Butte says. "There is safety in numbers."

And those numbers are rising rapidly. Since 2002, many scientific journals have required that data from gene-expression studies be deposited in public databases such as GEO, which is maintained by the National Center for Biotechnology Information in Bethesda, Maryland, and ArrayExpress, a large gene-expression

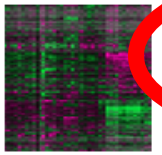
1. **Breast cancer**: histologically normal breast epithelium

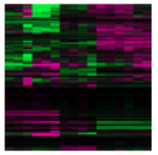


Analysis of histological normal breast epithelia from both ER- and ER+ **breast cancer** patients and prophylactic mastectomy patients, and normal breast epithelia from reduction mammoplasty patients. Results provide insight into the mechanisms underlying **breast cancer** initiation and progression.

Organism: Homo sapiens
Type: Expression profiling by array, count, 2 disease state, 4 specimen sets
Platform: GPL96 Series: GSE20437 42 Samples
Download data: GEO (CEL)

DataSet Accession: GDS3716 ID: 3716
PubMed Full text in PMC Similar studies GEO Profiles Analyze DataSet

2. Actein effect on **breast cancer** cell line: dose response and time course



Analysis of MDB-MB-453 **breast cancer** cells treated with 20 or 40 ug/ml actein for 6 or 24 hours. Actein is a triterpene glycoside from the herb black cohosh and inhibits the growth of cancer cells in vitro. Results provide insight into the molecular basis of this inhibitory effect.

Organism: Homo sapiens
Type: Expression profiling by array, transformed count, 2 agent, 3 dose, 2 time sets
Platform: GPL571 Series: GSE7848 16 Samples
Download data: GEO (CEL)

DataSet Accession: GDS3638 ID: 3638

ob/ob Diabetes Model - 16 Mice

Service Description

Provider: Links Biosciences is a US company with laboratories in Hangzhou, China. The laboratory has been offering exploratory (non-GLP) pharmacology services to US and Chinese biopharma since 2004.

Background: The obese mutant mouse model was first reported by Ingalls A *et al* from the Jackson Laboratory in 1951 (Obese, a New Mutation in the House Mouse [164 KB]). The obese mouse resulted from a spontaneous mutation in a gene that was named *ob* in the V stock. Mice homozygous for the obese spontaneous mutation, (Lep^ob^; commonly referred to as *ob* or *ob/ob*), are first recognizable at about 4 weeks of age. Homozygous mutant mice gain weight rapidly and may reach three times the weight of wild-type controls. In addition to obesity, mutant mice exhibit hyperphagia, a diabetes-like syndrome of hyperglycemia, glucose intolerance, elevated plasma insulin, subfertility, impaired wound healing, and an increase in hormone production from both pituitary and adrenal glands. Friedman J *et al* reported leptin in 1994, and demonstrated that leptin, the product of the *ob* gene, was produced in white adipose tissue and served as the peripheral signal to the central nervous system of nutritional status.

Service Details: This service offers a 28 day db/db mouse model of T2DM and obesity. Customer has various options that are conveyed to Links Biosciences using a Service Order Form. Customer assigns up to 16 mice to

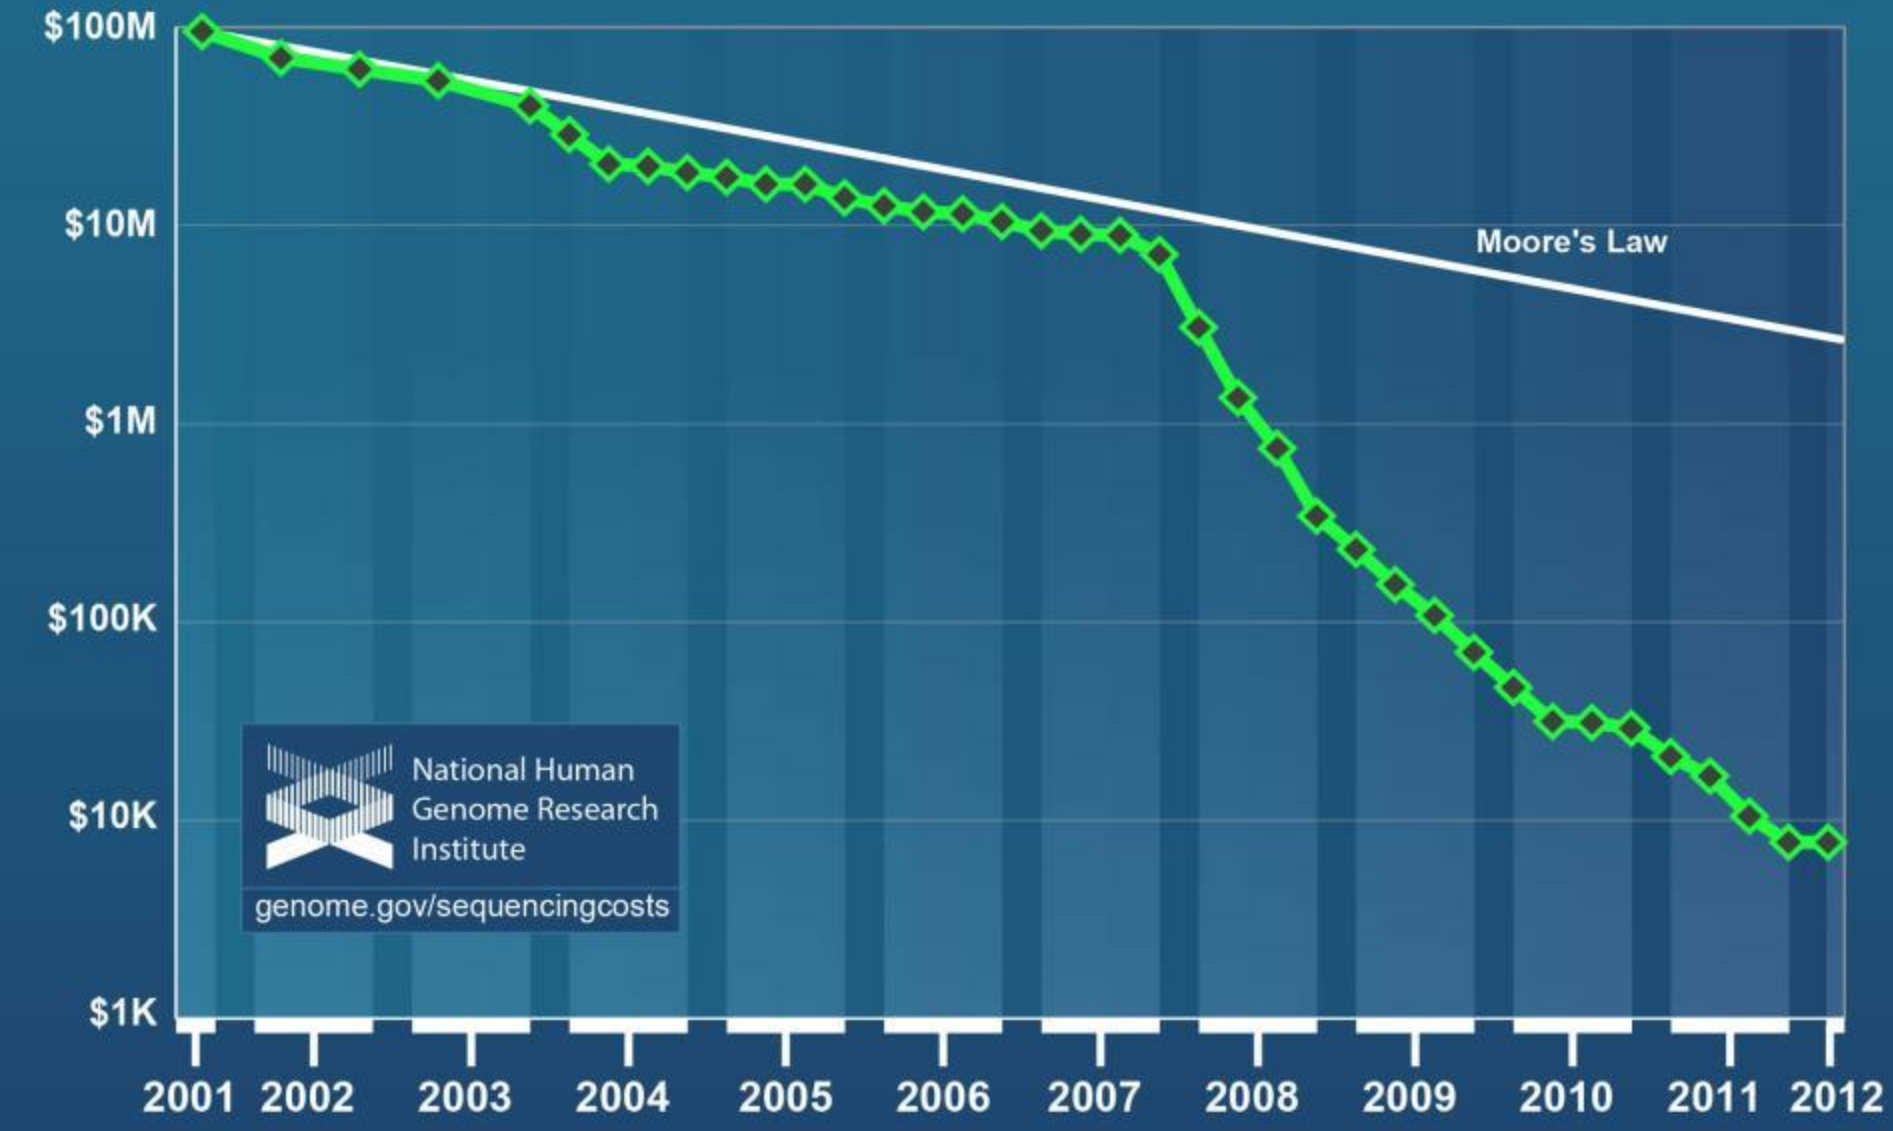
Cost per Genome



September 28, 2011

How Low Can We Go? Molecules, Photons, and Bits

Photons. The cost of photons is the cost of the optical and fluidic instrument designed to generate and capture photons from the fluorescent molecules. We can reduce the instrument cost per genome by successfully using more, faster cameras. Our current instruments are equipped with two electron multiplying charge coupled device (EMCCD) cameras. There is a new generation of fast complementary metal oxide semiconductor (CMOS) cameras, developed for other industries that are about 15 times faster than our current cameras (and also less expensive). New sequencing instruments that successfully use four of these fast new cameras could reduce the instrument cost per genome by about a factor of 30, from < $1,000 to $1,000/(2 x 15) or approximately $33 per genome.

Sample Sequence Data

Complete Genomics has recently made several complete human genome data sets available. The genomes were sequenced at the Complete Genomics commercial genome sequencing center in Mountain View, California as part our Complete Genomics Analysis Service (CGA™ Service). These data are largely consistent with the quality and attributes of other data provided to Complete Genomics customers.

When using these data in your research please cite the Complete Genomics website and our publication "Human Genome Sequencing Using Unchained Base Reads on Self-assembling DNA Nanoarrays." Science 1 January 2010 Vol. 327, no. 5961, pp. 78 - 81 DOI: 10.1126/science.1181498

Single-molecule sequencing of an individual human genome

Dmitry Pushkarev[1,2], Norma F Neff[1,2] & Stephen R Quake[1]

Recent advances in high-throughput DNA sequencing technologies have enabled order-of-magnitude improvements in both cost and throughput. Here we report the use of single-molecule methods to sequence an individual human genome. We aligned billions of 24- to 70-bp reads (32 bp average) to ~90% of the National Center for Biotechnology Information (NCBI) reference genome, with 28× average coverage. Our results were obtained on one sequencing instrument by a single operator with four data collection runs. Single-molecule sequencing enabled analysis of human genomic information without the need for cloning, amplification or ligation. We determined ~2.8 million single nucleotide polymorphisms (SNPs) with a false-positive rate of less than 1% as validated by Sanger sequencing and 99.8% concordance with SNP genotyping arrays. We identified 752 regions of copy number variation by analyzing coverage depth alone and validated 27 of these using digital PCR. This milestone should allow widespread application of genome sequencing to many aspects of genetics and human health, including personal genomics.

on a surface can be extended asynchronously, thereby allowing substantial flexibility in the kinetics of sequencing chemistry. Previous reports of single-molecule sequencing have been proofs of principle[11–13], and their sequencing throughput has not been competitive with alternative approaches. Generally, read lengths have been relatively short and error rates have been dominated by deletions; it has not been clear whether the resulting sequence quality is suitable for human genome sequencing applications.

The Heliscope Single Molecule Sequencer (Helicos Biosciences) is the first commercial release of a single-molecule sequencing instrument. It allows one to follow ~1 billion individual molecules as they are sequenced over the course of a week—a throughput that is practical for human genome sequencing. There have been several technical improvements to the platform since the reported sequencing of a viral genome[12], including more than a 1,000-fold improvement in parallelism, a new generation of sequencing reagents that allows digital measurement of homopolymer sequences, and a new software algorithm, IndexDP, for performing alignments to the entire human genome.

We used two of the instrument's 50 flow-cell channels to resequence

Clinical assessment incorporating a personal genome

Summary

Background The cost of genomic information has fallen steeply, but the clinical translation of genetic risk estimates remains unclear. We aimed to undertake an integrated analysis of a complete human genome in a clinical context.

Methods We assessed a patient with a family history of vascular disease and early sudden death. Clinical assessment included analysis of this patient's full genome sequence, risk prediction for coronary artery disease, screening for causes of sudden cardiac death, and genetic counselling. Genetic analysis included the development of novel methods for the integration of whole genome and clinical risk. Disease and risk analysis focused on prediction of genetic risk of variants associated with mendelian disease, recognised drug responses, and pathogenicity for novel variants. We queried disease-specific mutation databases and pharmacogenomics databases to identify genes and mutations with known associations with disease and drug response. We estimated post-test probabilities of disease by applying likelihood ratios derived from integration of multiple common variants to age-appropriate and sex-appropriate pre-test probabilities. We also accounted for gene-environment interactions and conditionally dependent risks.

ORIGINAL ARTICLE

Association of *IL23R*, *TNFRSF1A*, and HLA-DRB1*0103 Allele Variants with Inflammatory Bowel Disease Phenotypes in the Finnish Population

Maarit Lappalainen, MSc,[*†] Leena Halme, MD, PhD,[‡] Ulla Turunen, MD,[§] Päivi Saavalainen, PhD,*[|] Elisabet Einarsdottir, PhD,*[|] Martti Färkkilä, MD, PhD,[§] Kimmo Kontula, MD, PhD,*[†] and Paulina Paavola-Sakki, MD, PhD[†,§]*

Background: Crohn's disease (CD) and ulcerative colitis (UC), 2 major forms of inflammatory bowel disease (IBD), are complex disorders with significant genetic predisposition. The first CD-associated gene, *CARD15/NOD2*, was recently identified and since then several reports on novel IBD candidate genes have emerged. We investigated disease phenotype association to genetic variations in *IL23R, ATG16L1, DLG5, ABCB1/MDR1, TLR4, TNFRSF1A*, chromosome 5 risk haplotype including *SLC22A4* and *SLC22A5*, and HLA-DRB1*0103 allele among Finnish IBD patients.

Methods: A total of 699 IBD patients were genotyped for disease-associated variants by polymerase chain reaction (PCR) and restriction enzyme digestion or Sequenom iPLEX method.

Results: Five markers spanning the *IL23R* gene were associated with CD. The SNP (single nucleotide polymorphism) rs2201841 gave the strongest association ($P = 0.002$). The rare HLA-DRB1*0103 allele was found to associate with UC ($P = 0.008$), and the *TNFRSF1A* A36G variant was associated with familial UC ($P = 0.007$). Upon phenotypic analysis we detected association between familial UC and rare *TNFRSF1A* alleles 36G and IVS6+10G ($P = 0.001$ and $P = 0.042$, respectively). In addition, *IL23R* markers were associated with stricturing CD ($P = 0.010–0.017$), and ileocolonic CD was more prevalent in the carriers of the same 2 *TNFRSF1A* variants ($P = 0.021$ and $P = 0.028$, respectively). Less significant genotype–phenotype associations were observed for the *TLR4* and HLA variants.

Conclusions: We were able to replicate the association of the *IL23R* variants with CD as well as HLA-DRB1*0103 with UC; confirmation of *TNFRSF1A* association with UC needs additional studies. Our findings also suggest that polymorphisms at *IL23R* and *TNFRSF1A*, and possibly HLA and *TLR4*, loci may account for phenotypic variation in IBD.

(*Inflamm Bowel Dis 2008;14:1118–1124*)

Key Words: Finnish, inflammatory bowel disease, HLA-DRB1*0103, IL23R, TNFRSF1A

Since the initial discovery of the association of *CARD15/NOD2* gene variants with Crohn's disease (CD),[1–3] several new susceptibility genes for inflammatory bowel disease (IBD) have been reported. In 2004 the positional cloning approach led to the identification of the associated variants in solute carrier family 22 (*SLC22A* members 4 and 5)[4] and the discs large homolog 5 (*DLG5*)[5] genes that are implicated in fatty acid oxidation and in maintaining epithelial integrity, respectively. It has not, however, been unequivocally proved that the *SLC22A* genes represent the actual disease genes.[6–13] Most of the studies have confirmed the association of CD with the *SLC22A* gene variants or with the chromosome 5 risk haplotype; however, a study of more than 981 Belgian IBD patients could not replicate the association with IBD, CD, or ulcerative colitis (UC).[14] A recent study by Silverberg et al[15] using a large cohort of IBD trios excluded the *SLC22A5* gene variant as the potential causal variant. The association of genetic variations in the *DLG5* gene with IBD and CD was initially described in 2 large European study samples.[5] The haplotype A, tagged by SNP DLG5_e26 ins/delA, was significantly undertransmitted in IBD and CD, whereas haplotype D, tagged by the SNP G113A (R30Q), was significantly overtransmitted in both IBD and CD. Several groups have not been able to replicate the association since the original report.[13,14,16] However, in 1 case gender-specific analysis revealed an association.[17]

The association of IBD with genetic variation in the Toll-like receptor 4 (*TLR4*) gene has been investigated by many groups but the results have been controversial, which

Association of *IL23R*, *TNFRSF1A*, and HLA-DRB1*0103 Allele Variants with Inflammatory Bowel Disease Phenotypes in the Finnish Population

Maarit Lappalainen, MSc,[*†] *Leena Halme, MD, PhD,*[‡] *Ulla Turunen, MD,*[§] *Päivi Saavalainen, PhD,*[*|] *Elisabet Einarsdottir, PhD,*[*|] *Martti Färkkilä, MD, PhD,*[§] *Kimmo Kontula, MD, PhD,*[*†] *and Paulina Paavola-Sakki, MD, PhD*[†,§]

Background: Crohn's disease (CD) and ulcerative colitis (UC), 2 major forms of inflammatory bowel disease (IBD), are complex disorders with significant genetic predisposition. The first CD-associated gene, *CARD15/NOD2*, was recently identified and since then several reports on novel IBD candidate genes have emerged. We investigated disease phenotype association to genetic variations in *IL23R, ATG16L1, DLG5, ABCB1/MDR1, TLR4, TNFRSF1A*, chromosome 5 risk haplotype including *SLC22A4* and *SLC22A5*, and HLA-DRB1*0103 allele among Finnish IBD patients.

Methods: A total of 699 IBD patients were genotyped for disease-associated variants by polymerase chain reaction (PCR) and restriction enzyme digestion or Sequenom iPLEX method.

Conclusions: We were able to replicate the association of the *IL23R* variants with CD as well as HLA-DRB1*0103 with UC; confirmation of *TNFRSF1A* association with UC needs additional studies. Our findings also suggest that polymorphisms at *IL23R* and *TNFRSF1A*, and possibly HLA and *TLR4*, loci may account for phenotypic variation in IBD.

port.[13,14,16] However, in 1 case gender-specific analysis revealed an association.[17]

The association of IBD with genetic variation in the Toll-like receptor 4 (*TLR4*) gene has been investigated by many groups but the results have been controversial, which

Moving from OR to LR

Odds ratio

Ratio of odds of test positivity in cases over odds of test positivity in non-cases

Likelihood ratio (+)

The probability of test positive in cases, over the probability of test positive in non-cases

Sensitivity / (1 – Specificity)

Very similar, but different...

Morgan A, Chen R, Butte AJ. *Genomic Medicine*, 2010.

Post-test probability is calculated with likelihood ratio

Pre-test odds x likelihood ratio → Post-test odds

Pre-test odds x LR1 x LR2 x LR3 → Post-test odds

Can chain likelihood ratios from independent tests

Morgan A, Chen R, Butte AJ. *Genomic Medicine*, 2010.

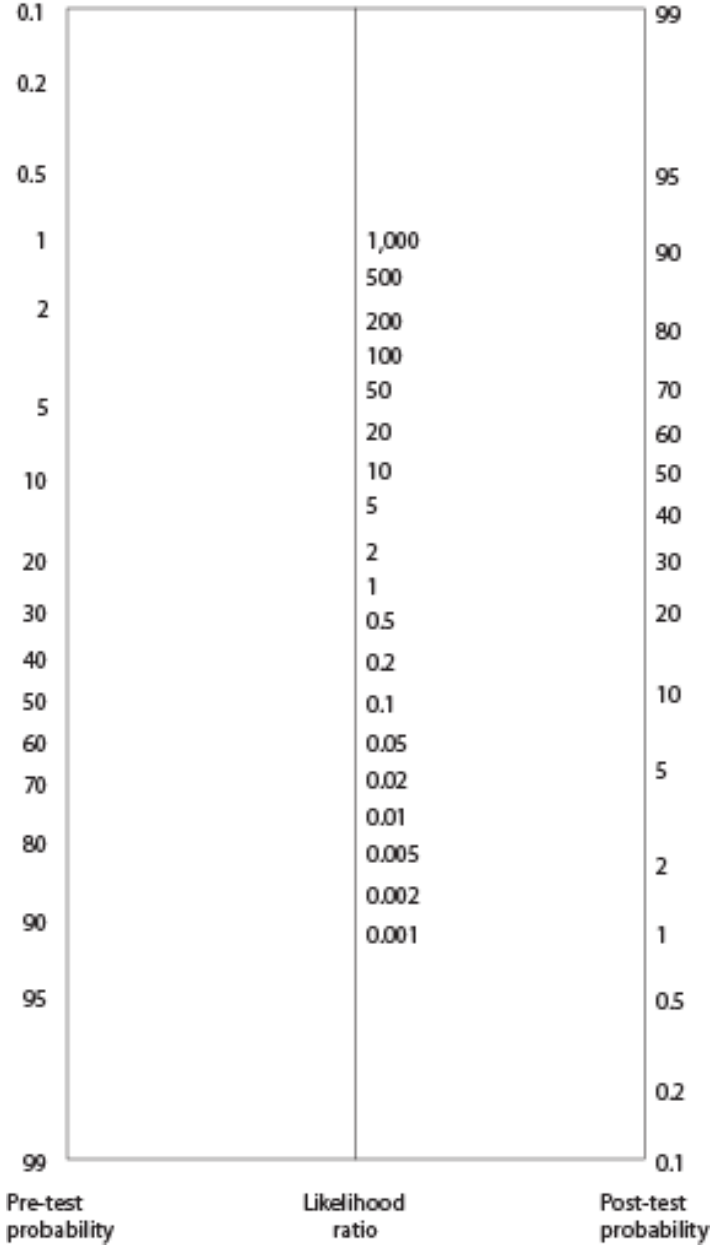

Figure 1. Nomogram for likelihood ratios. The pre-test and post-test probabilities and likelihood ratios of any diagnostic test, including a genetic test, can be visualized using a nomogram familiar to most physicians and medical students. The nomogram shown is derived from the Fagan nomogram [14], and modified from one generated using a web-based tool [28]. The left side of the figure indicates a hypothetical pre-test probability of disease of 27%. Three lines represent the three possible genotypes, from top to bottom: homozygous risk alleles with a likelihood ratio of 1.61, heterozygous alleles with a likelihood ratio of 1.26, and homozygous protective alleles with a likelihood ratio of 0.83. The right side of the figure indicates three possible post-test probabilities resulting from the three genotypes. Multiple such tests can be 'chained' together serially, if they describe independent risks and cover the same pre-test assumptions.

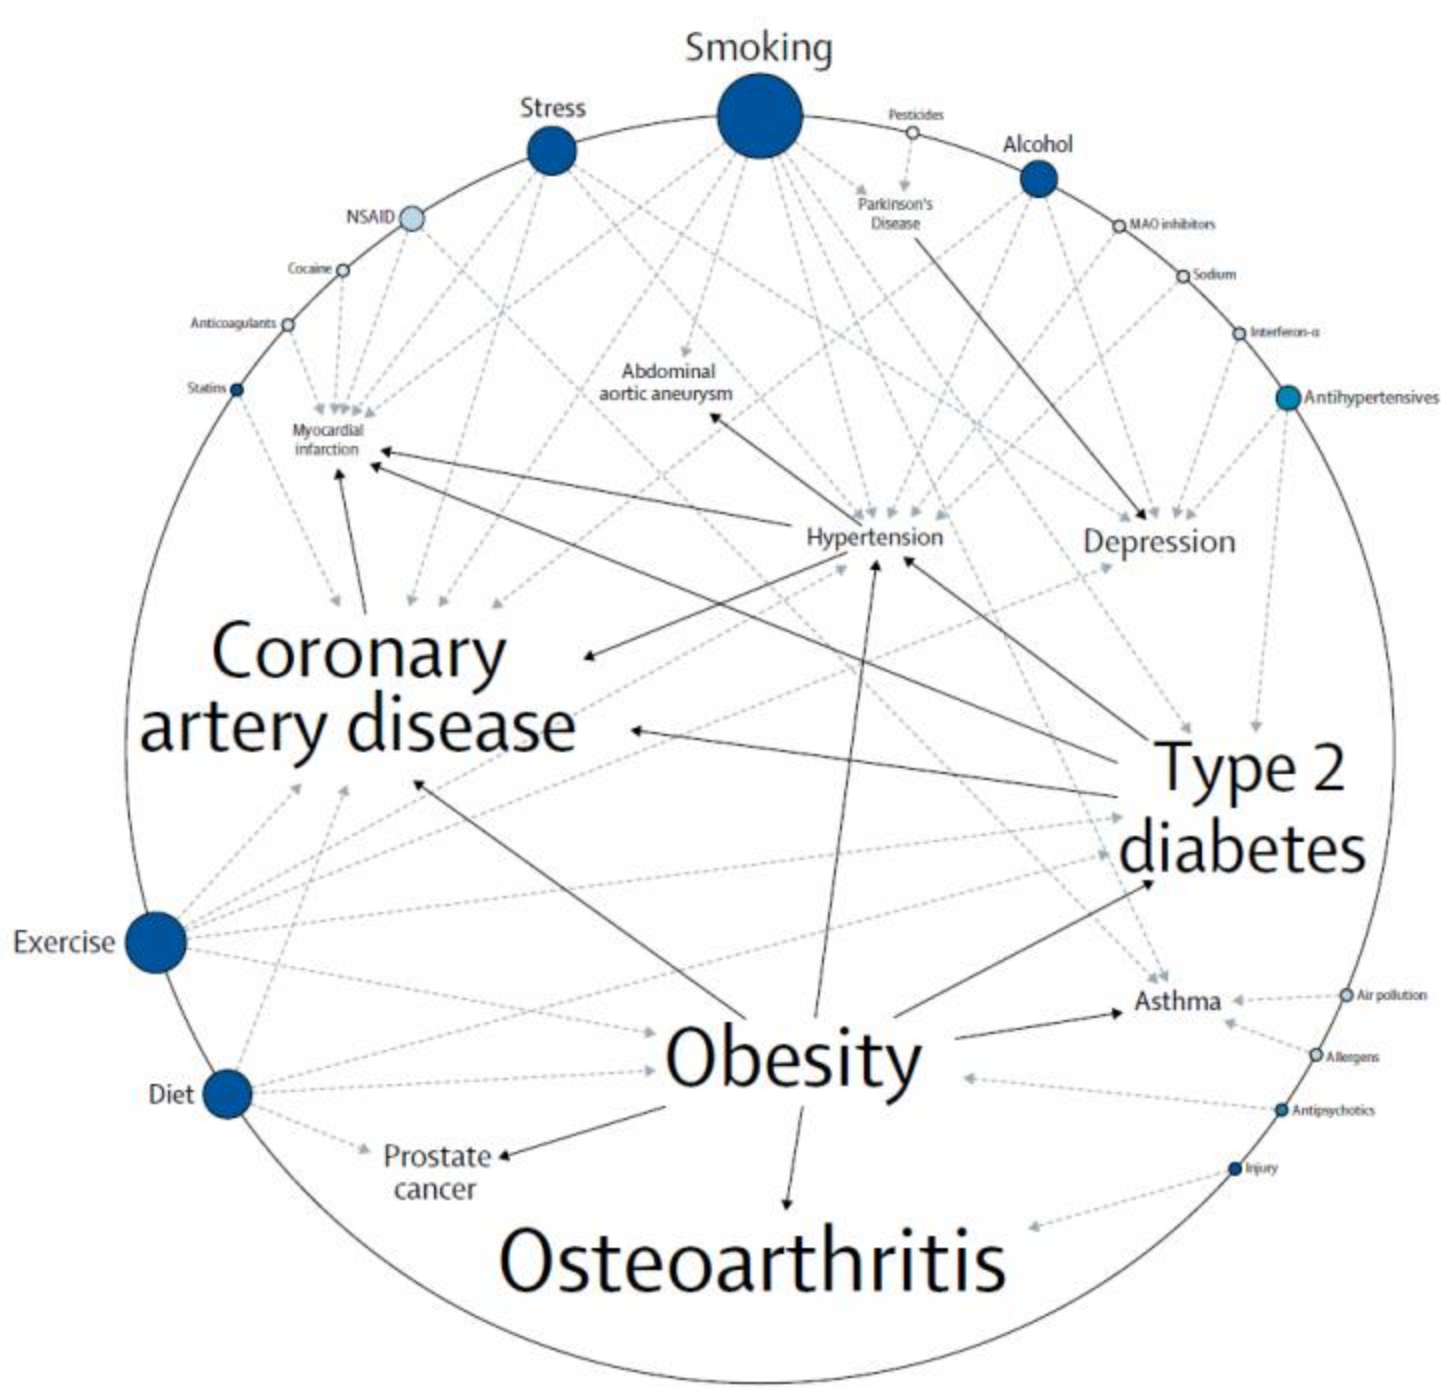
So what can we do about the risk?

- Diseases with higher post-test probabilities
- How to alter the influence of genetics?

- Diseases are caused by genes and environment

- We need a simple "prescription" for environmental change for a genome-enabled patient

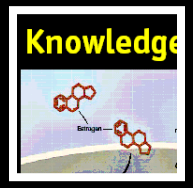
- How do we compensate for our genomes?



Rong Chen
Alex Morgan
Joel Dudley

Take Home Points

- Molecular, clinical, trials, and epidemiological data and tools already exist → diagnostics and therapeutics.



- Public big data is highly enabling.
  Use it, and share your data after publication.

- Personalized medicine $\geq$ DNA. Needs to include other clinical, molecular, and environment measures.
